

4.19	Effectiveness of the degree-based, distance-based, RMD-based, and anonymous policies on the <i>moderate</i> ₁ HCW contact networks measured by the expected number of people infected as a result of simulation of an SIR disease diffusion simulation with peak transmission probability $p = .5$. The x -axis represents the budget of vaccinations as a fraction of the total population. The y -axis represents the expected fraction of the population infected based on experiments.	140
4.20	Example graph of communities with high weight intra-community edges and low weight edges between communities. Thin lines represent low-weight edges and thick lines represent high-weight edges. Communities are circled by a dotted line.	141
4.21	Comparison of the effectiveness of the mincut-degree-based policy and degree-based policy. Policies are generate from the <i>moderate</i> ₁ graph for time window $T = 1$, peak transmission probability $p = .07$, and <i>thresh</i> = .3	144
4.22	Comparison of the effectiveness of the mincut-degree-based policy and degree-based policy. Policies are generate from the <i>moderate</i> ₁ graph for time window $T = 1$, peak transmission probability $p = .1$, and <i>thresh</i> = .3	145
4.23	Comparison of the effectiveness of the mincut-degree-based policy, and degree-based policy. Policies are generate from the <i>moderate</i> ₁ graph for time window $T = 1$, peak transmission probability $p = .5$, and <i>thresh</i> = .5	146
4.24	Trimming of boundary vertices as a result of the mincut percolation process.	146
5.1	Summary statistics for all EIN traffic from February 1997 through May 2009 including the average (\pm standard deviation), minimum, and maximum number of mailings, number of posts, and number of users per thread.	156
5.2	Data on classification of important threads. (a) percentage of threads whose number of mailings, number of posts, and number of participants are all within <i>thresh</i> % of the corresponding maximum values of these characteristics. Since $T^+(thresh) \supseteq T^+(thresh')$ for $thresh > thresh'$, we obtain larger sets of important threads as we increase <i>thresh</i> from 60 to 80. With $x = 60$, we pick up 18 (out of 2818) important threads, with $x = 70$, we pick up 47 (out of 2818) important threads, and with $x = 80$, we pick up 183 (out of 2818) important threads. (b) Aggregate statistics of important threads for different values of <i>thresh</i>	158
